```

Q1. How many genes are in this dataset?

38694.

```
library(dplyr)

# Find the control samples
control_samples <- metadata %>% filter(dex == "control")

# Find the number of unique cell lines from control samples
length(unique(control_samples$celltype))
```

```
[1] 4
```

Q2. How many 'control' cell lines do we have?

4 control cell lines.

4. Try differential expression

Lets perform some exploratory differential gene expression analysis. Note: this analysis is for demonstration only. NEVER do differential expression analysis this way!

Q3. How would you make the above code in either approach more robust? Is there a function that could help here?

You need to parameterize the number of control and treated samples.

```
# Find the id for control samples
control_samples$id
```

```
[1] "SRR1039508" "SRR1039512" "SRR1039516" "SRR1039520"
```

```
# Find the counts for control samples
control.counts <- counts[,control_samples$id]
control.mean <- rowSums(control.counts)/ncol(control_samples)

head(control.mean)
```

```
ENSG00000000003 ENSG00000000005 ENSG00000000419 ENSG00000000457 ENSG00000000460
         900.75            0.00          520.50          339.75           97.25
ENSG00000000938
           0.75
```

Q4. Follow the same procedure for the treated samples (i.e. calculate the mean per gene across drug treated samples and assign to a labeled vector called treated.mean)

Repeat for treated samples.

```
# Find the treated samples
treated_samples <- metadata %>% filter(dex == "treated")

# Find the id for control samples
treated_samples$id
```

```
[1] "SRR1039509" "SRR1039513" "SRR1039517" "SRR1039521"
```

```
# Find the counts for control samples
treated.counts <- counts[,treated_samples$id]
treated.mean <- rowSums(treated.counts)/ncol(treated_samples)
```

```
head(treated.mean)
```

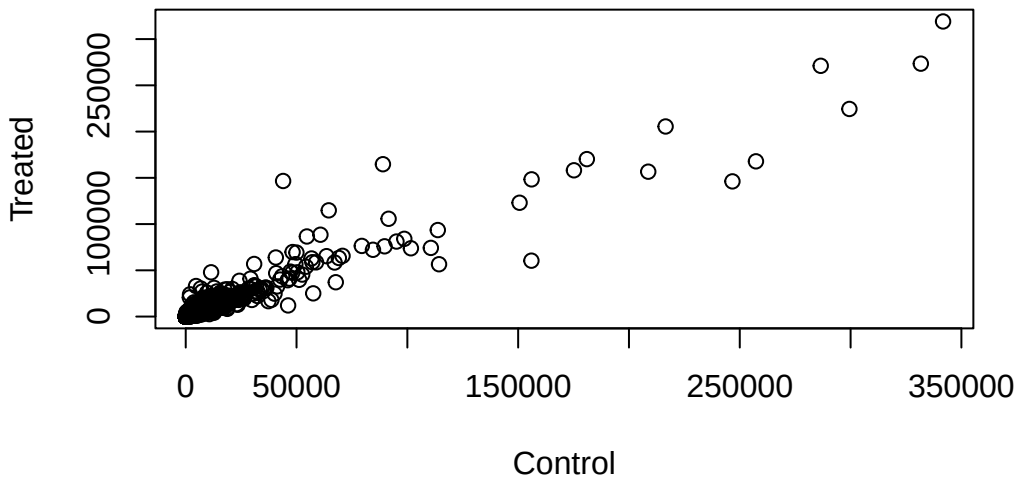
```
ENSG00000000003 ENSG00000000005 ENSG00000000419 ENSG00000000457 ENSG00000000460
         658.00            0.00          546.00          316.50           78.75
ENSG00000000938
           0.00
```

```
meancounts <- data.frame(control.mean, treated.mean)
colSums(meancounts)
```

```
control.mean treated.mean
    23005324     22196524
```

##Q5 (a). Create a scatter plot showing the mean of the treated samples against the mean of the control samples. Your plot should look something like the following.

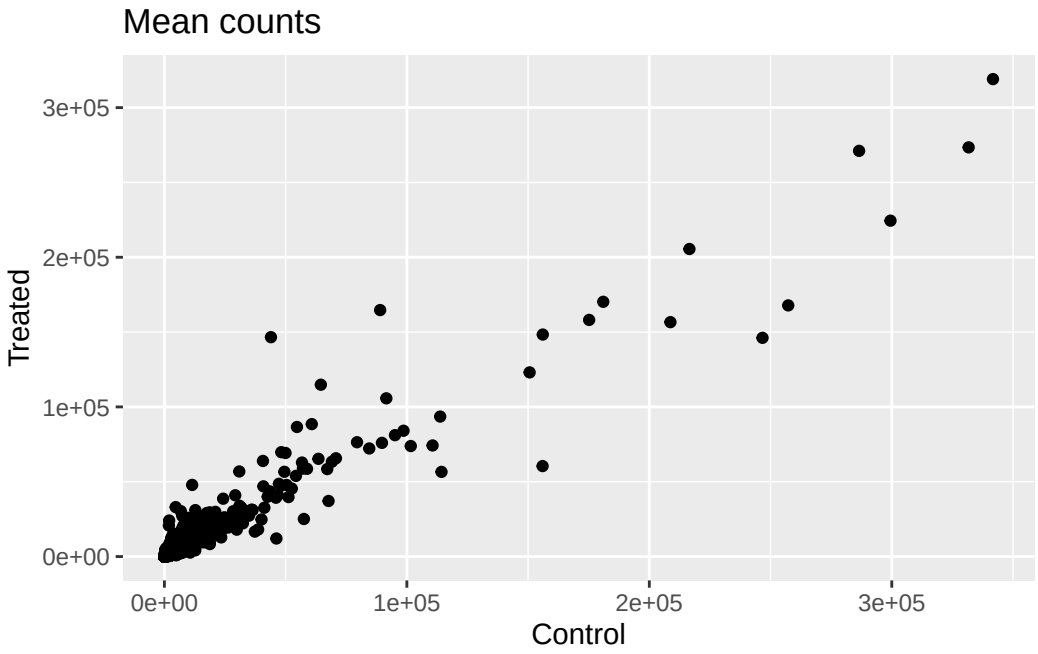
```
plot(meancounts$control.mean, meancounts$treated.mean, xlab = "Control",
     ylab = "Treated")
```



##Q5 (b).You could also use the ggplot2 package to make this figure producing the plot below. What geom_?() function would you use for this plot?

```
library(ggplot2)

ggplot(meancounts, aes(x = meancounts[,1], y = meancounts[,2])) +
  geom_point() +
  labs(x = "Control", y = "Treated", title = "Mean counts")
```

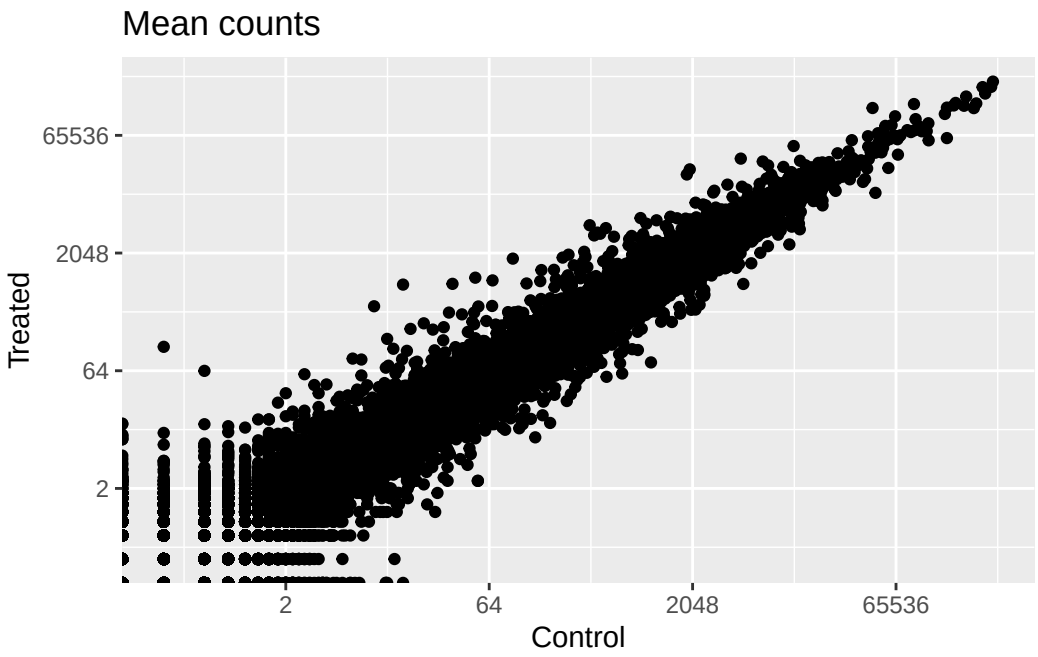


##Q6. Try plotting both axes on a log scale. What is the argument to plot() that allows you to do this?

```
ggplot(meancounts, aes(x = meancounts[,1], y = meancounts[,2])) +
  geom_point() +
  labs(x = "Control", y = "Treated", title = "Mean counts") +
  scale_x_continuous(trans = "log2") + scale_y_continuous(trans = "log2")
```

```
Warning: Transformation introduced infinite values in continuous x-axis
```

```
Warning: Transformation introduced infinite values in continuous y-axis
```



```
# Calculate log2 foldchange for these mean counts
meancounts$log2fc <- log2(meancounts[,"treated.mean"]/meancounts[,"control.mean"])
head(meancounts)
```

```
                control.mean treated.mean      log2fc
ENSG00000000003       900.75       658.00 -0.45303916
ENSG00000000005         0.00         0.00         NaN
ENSG00000000419       520.50       546.00  0.06900279
ENSG00000000457       339.75       316.50 -0.10226805
ENSG00000000460        97.25        78.75 -0.30441833
ENSG00000000938         0.75         0.00        -Inf
```

Trying to divide by 0 triggers an NaN, -Inf is trying to take the log of 0.

```
# Find indexes of zero values from either sample and collapse to unique list
zero.vals <- which(meancounts[,1:2]==0, arr.ind = TRUE)
to.rm <- unique(zero.vals[,1])

nonzero.counts <- meancounts[-to.rm,]
head(nonzero.counts)
```

```
                control.mean treated.mean      log2fc
ENSG00000000003       900.75       658.00 -0.45303916
ENSG00000000419       520.50       546.00  0.06900279
ENSG00000000457       339.75       316.50 -0.10226805
ENSG00000000460        97.25        78.75 -0.30441833
ENSG00000000971      5219.00      6687.50  0.35769358
ENSG00000001036      2327.00      1785.75 -0.38194109
```

Q7. What is the purpose of the arr.ind argument in the which() function call above? Why would we then take the first column of the output and need to call the unique() function?

`arr.ind` tells the `which()` function to return the index of the data we are looking for, which we need to know to be able to remove it. We need to take the first column of the result because this tells us the index of zero values. We need to call `unique()` on it to ensure we aren't trying to remove genes twice if they have 0 reads in both the control and treated samples.

We want to filter the data for log fold changes above 2 or below -2.

```
up.ind <- nonzero.counts$log2fc > 2
down.ind <- nonzero.counts$log2fc < (-2)
```

Q8. Using the up.ind vector above can you determine how many up regulated genes we have at the greater than 2 fc level?

##Q9. Using the down.ind vector above can you determine how many down regulated genes we have at the greater than 2 fc level?

```
up_genes <- nonzero.counts[up.ind,]
down_genes <- nonzero.counts[down.ind,]

nrow(up_genes)
```

```
[1] 250
```

```
nrow(down_genes)
```

```
[1] 367
```

250 genes are upregulated and 367 are downregulated.

Q10. Do you trust these results? Why or why not?

No. We haven't calculated any kind of test statistic so we don't have a measure of whether these differences are statistically significant.

[1] see 'cooksCutoff' argument of ?results
[2] see 'independentFiltering' argument of ?results
```

The reason there are so many uncalculated adjusted p values is that DEseq is removing genes that are unlikely to show statistically significant changes in expression (based on overall expression levels) before calculating these values to increase the detection power and reduce type I errors.
